

FlexiShard

Tirathraj Ramburn & Dhrubajyoti Goswami

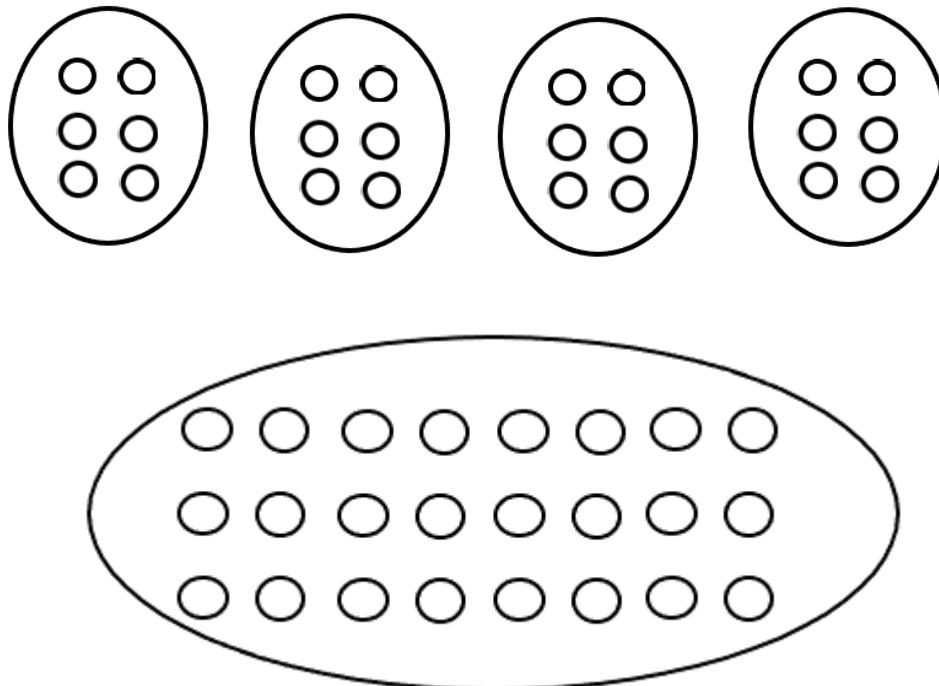

Concordia University, Canada

FlexiShard: a Flexible Sharding Scheme for Blockchain based on a Hybrid Fault Model

Agenda

- ▶ Bitcoin & Scalability
- ▶ Sharding & Shard Size
- ▶ Network Model & Intra-Shard BFT Consensus
- ▶ Hybrid Fault Model
- ▶ Flexible BFT
- ▶ FlexiShard & its Schemes

Bitcoin does not Scale Out

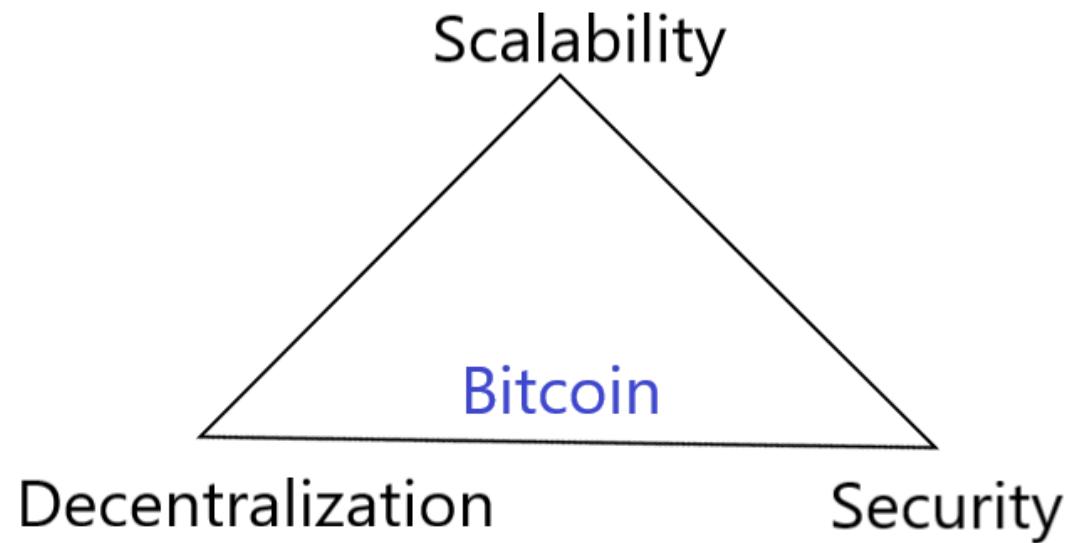

- ▶ Sharding
 - ▶ m shards: m blocks every 10 minutes
 - ▶ Linear increase in throughput with number of shards
- ▶ Bitcoin
 - ▶ 1 shard: 1 block every 10 minutes
 - ▶ Adding more resources does not increase throughput
 - ▶ Improve throughput for crypto adoption as transactional currency

Bitcoin's Throughput: ≈ 5 transactions per second

Visa's Throughput: ≈ 1700 transactions per second

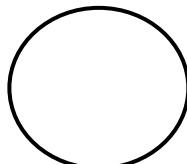

CAP Theorem / Blockchain Trilemma

- ▶ Pick one side of triangle
- ▶ Sharding lowers collective security of a system

Shard Size

Small shard

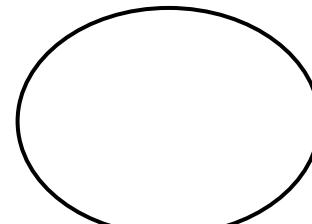

- ▶ Performance inside shard ↑
(small number of message exchanges)

- ▶ More shards = throughput ↑

- ▶ Security ↓

Large shard

- ▶ Performance inside shard ↓
(large number of message exchanges)

- ▶ Less shards = throughput ↓

- ▶ Security ↑

Aim : Middle ground between size (performance) & security

Network Model

Synchrony

- ▶ Message delivery bounded by fixed time ▲ (delta)
- ▶ If $\Delta = 10$ seconds, 6 blocks per minute
- ▶ Nonresponsive
- ▶ Δ is a conservative value
- ▶ Wait for 10 seconds even if all messages delivered in 1 second

Partial Synchrony

- ▶ Message delivery occurs at actual network delay α (alpha)
- ▶ If $\alpha \approx 1$ second, 60 blocks per minute
- ▶ Responsive
- ▶ More practical

Aim:
Use Partial Synchrony

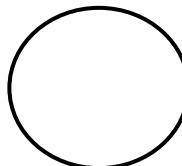

Fault/Adversarial Model

Traditional Systems

- ▶ Byzantine faults only
 - ▶ Arbitrary/Unpredictable behaviour
 - ▶ Attack Safety + Liveness
 - ▶ Most powerful type of fault
- ▶ Safety
 - ▶ Double-spend attack
 - ▶ Equivocation of values such as Merkle Root
 - ▶ Falsifying user balances
- ▶ Liveness
 - ▶ Preventing progress of system
 - ▶ Cutting off communication channels

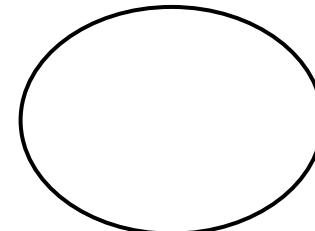

BFT Consensus Algorithms

Synchronous BFT

- ▶ $f < m/2$
- ▶ shard size, $m = 300$; $f \leq 149$
- ▶ More resilience = smaller shard size
 - ▶ Threshold = 10^{-10} : size ≈ 300
- ▶ Nonresponsive
- ▶ (RapidChain)

Partially Synchronous BFT

- ▶ $f < m/3$
- ▶ $m = 300$; $f \leq 99$
- ▶ Less resilience = larger shard size
 - ▶ Threshold = 10^{-10} : size $\approx 700 - 800$
- ▶ Responsive
- ▶ (OmniLedger)

Aim : shard size comparable to RapidChain's but Responsive

Aim : Small Shard + Partial Synchrony (best of both worlds)

Fault/Adversarial Model

Traditional Systems

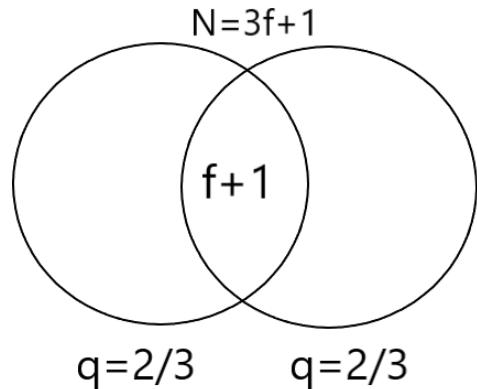

- ▶ Byzantine faults only
 - ▶ Arbitrary/Unpredictable behaviour
 - ▶ Attack Safety + Liveness
 - ▶ Most powerful type of fault
- ▶ Safety
 - ▶ Double-spend attack
 - ▶ Equivocation of values such as Merkle Root
 - ▶ Falsifying user balances
- ▶ Liveness
 - ▶ Preventing progress of system
 - ▶ Cutting off communication channels

FlexiShard

- ▶ Hybrid Fault Model
- ▶ Byzantine + abc faults
- ▶ abc : alive-but-corrupt faults
 - ▶ Attack Safety only
 - ▶ Collaborate to make progress if node cannot attack safety
 - ▶ More practical

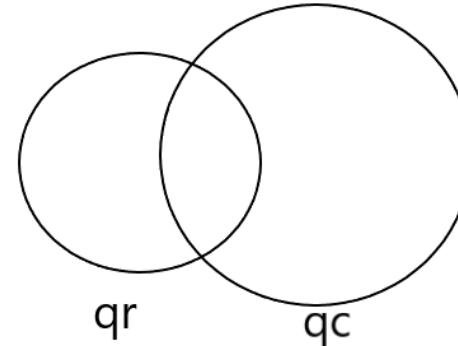

Partially Synchronous Consensus Algorithms

Classic BFT

- ▶ $q = 2f+1 / 3f+1 \approx 2/3$ (optimal)
- ▶ PBFT : 2 rounds of voting
- ▶ $2f+1$ identical votes per round
- ▶ Byzantine only
- ▶ $F < 2q - 1$
 - ▶ $byzF < 2q - 1$
 - ▶ $abc = 0$

Flexible BFT

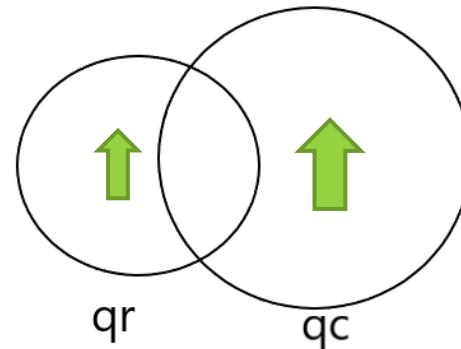

- ▶ Byzantine + abc faults
- ▶ $qc \geq qr$
- ▶ $F < qr + qc - 1$
 - ▶ $byzF \leq 1 - qc$
 - ▶ $abc < F - byzF$
 - ▶ $abc < qr + 2qc - 2$

Partially Synchronous Consensus Algorithms

Flexible BFT Properties

- ▶ Byzantine + abc faults
- ▶ $qc \geq qr$
- ▶ $F < qr + qc - 1$
 - ▶ $byzF \leq 1 - qc$
 - ▶ $abc < F - byzF$
- ▶ Classic BFT
 - ▶ $\uparrow q$: Lose Liveness (Quorum Availability)
 - ▶ $\downarrow q$: Lose Safety (Quorum Intersection)
 - ▶ $q = 2/3$ is optimal

↑ quorum size qr or qc or both :

Total number of faults ↑

Byzantine faults ↓

abc faults ↑

Rate of abc ↑ > Rate of Byz ↓

Shard size, $m = 300$

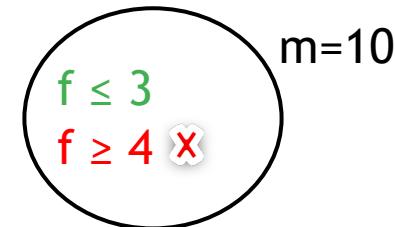

- ▶ Traditional
- ▶ FlexiShard 1
- ▶ FlexiShard 2
- ▶ FlexiShard 3
- ▶ Byzantine only
- ▶ Byz+ abc
- ▶ Byz+ abc
- ▶ Byz+ abc
- ▶ $qr = 2/3$
- ▶ $qc = 2/3$
- ▶ $qc = 0.75$
- ▶ $qc = 0.9$
- ▶ $qc = 1$
- ▶ 
- ▶ Total F ≤ 99 (33%)
- ▶ Total F ≤ 125 (41%)
- ▶ Total F ≤ 170 (56%)
- ▶ Total F ≤ 199 (66%)
- ▶ ByzF ≤ 99 (33%)
- ▶ ByzF ≤ 75 (25%)
- ▶ ByzF ≤ 30 (10%)
- ▶ ByzF = 0 (0%)
- ▶ abcF = 0 (0%)
- ▶ abcF = 50 (16%)
- ▶ abcF = 140 (46%)
- ▶ abcF = 199 (66%)
- ▶ Rigid/Conservative
- ▶ Practical
- ▶ Practical
- ▶ Very Optimistic

Perfect Shards

- ▶ Shards are assumed to be **PERFECT**
- ▶ Hence shards **always** produce correct results
- ▶ Need to form shards with **NEGLIGIBLE** (very low) failure probability

Calculation of Shard Failure probability (Traditional)

- ▶ BOUND THE FAILURE PROBABILITY
 - ▶ Actual failure probability never exceeds bounded probability (overestimation)
- ▶ m : shard size, F : total faults in system, N : total nodes in system, X : actual num of byz faults in shard
- ▶ Partial Sync, Byz only, $f < m/3$
- ▶ $m=10$, $f \leq 3$ for safety or $f \geq 4$ for failure
- ▶ **Shard has failed when we have 4 faults OR 5 faults OR 6 faults OR ... 10 faults.**
- ▶ $P_{Faulty} = P(f=4) + P(f=5) \dots + P(f=10)$

$$P_{Faulty} = P\left(f \geq \left\lfloor \frac{m}{3} \right\rfloor\right) = \sum_{x=\left\lfloor \frac{m}{3} \right\rfloor}^m \frac{\binom{F}{x} \binom{N-F}{m-x}}{\binom{N}{m}}$$

Calculation of Shard Failure probability (FlexiShard)

- ▶ BOUND THE FAILURE PROBABILITY
 - ▶ Actual failure probability never exceeds bounded probability (overestimation)
 - ▶ m : shard size, F : total faults in system, N : total nodes in system, X : actual num of byz faults in shard
 - ▶ Partial Sync, Byz + abc
 - ▶ $m=10$, $f_{\text{byz}} \leq 4$ and $f_{\text{abc}} \leq 4$ for safety
- ▶ Shard has failed when either byz or abc threshold exceeded
 - ▶ $P_{\text{Faulty}} = P(f_{\text{byz}} \geq 5) \text{ OR } P(f_{\text{abc}} \geq 5)$
- ▶ Therefore, shard is safe when both type of faults are within their respective bounds
 - ▶ $P_{\text{NonFaulty}} = P(f_{\text{byz}} \leq 4) \text{ AND } P(f_{\text{abc}} \leq 4)$

Calculation of Shard Failure probability (FlexiShard)

- ▶ Shard is safe when both type of faults are within their respective bounds

- ▶ $P_{\text{NonFaulty}} = P(f_{\text{byz}} \leq 4) \text{ AND } P(f_{\text{abc}} \leq 4)$

- ▶ $P_{\text{Faulty}} = 1 - P_{\text{NonFaulty}}$

- ▶ Calculate all possibilities that a shard is safe:

$$P_{\text{NonFaulty}} = P(f_{\text{byz}} = 0 \text{ AND } f_{\text{abc}} = 0) + P(f_{\text{byz}} = 0 \text{ AND } f_{\text{abc}} = 1) \dots + P(f_{\text{byz}} = 0 \text{ AND } f_{\text{abc}} = 4)$$

$$+ P(f_{\text{byz}} = 1 \text{ AND } f_{\text{abc}} = 0) + P(f_{\text{byz}} = 1 \text{ AND } f_{\text{abc}} = 1) \dots + P(f_{\text{byz}} = 1 \text{ AND } f_{\text{abc}} = 4)$$

.

.

$$+ P(f_{\text{byz}} = 4 \text{ AND } f_{\text{abc}} = 0) + P(f_{\text{byz}} = 4 \text{ AND } f_{\text{abc}} = 1) \dots + P(f_{\text{byz}} = 4 \text{ AND } f_{\text{abc}} = 4)$$

- ▶ $P_{\text{Faulty}} = 1 - P_{\text{NonFaulty}}$

Calculation of Shard Failure probability (FlexiShard)

- ▶ Hypergeometric Distribution Formula for mixed fault model: byzantine + abc faults

$$\begin{aligned} P_{NonFaultyFlexi} &= P(Y \leq f_{abc} \text{ AND } Z \leq f_{byz}) \\ &= \frac{\sum_{byz=0}^{f_{byz}} \binom{FB}{byz} \times \left(\sum_{abc=0}^{f_{abc}} \binom{FA}{abc} \times \binom{N-F}{m-byz-abc} \right)}{\binom{N}{m}} \\ &= \frac{\sum_{byz=0}^{\lfloor ((1-qc) \times m) \rfloor} \binom{(\lfloor byzProp * F \rfloor)}{byz}}{\binom{N}{m}} \\ &\times \left(\sum_{abc=0}^{\lfloor ((qr+2qc-2) \times m) \rfloor} \binom{F - (\lfloor byzProp * F \rfloor)}{abc} \times \binom{N-F}{m-byz-abc} \right) \end{aligned}$$

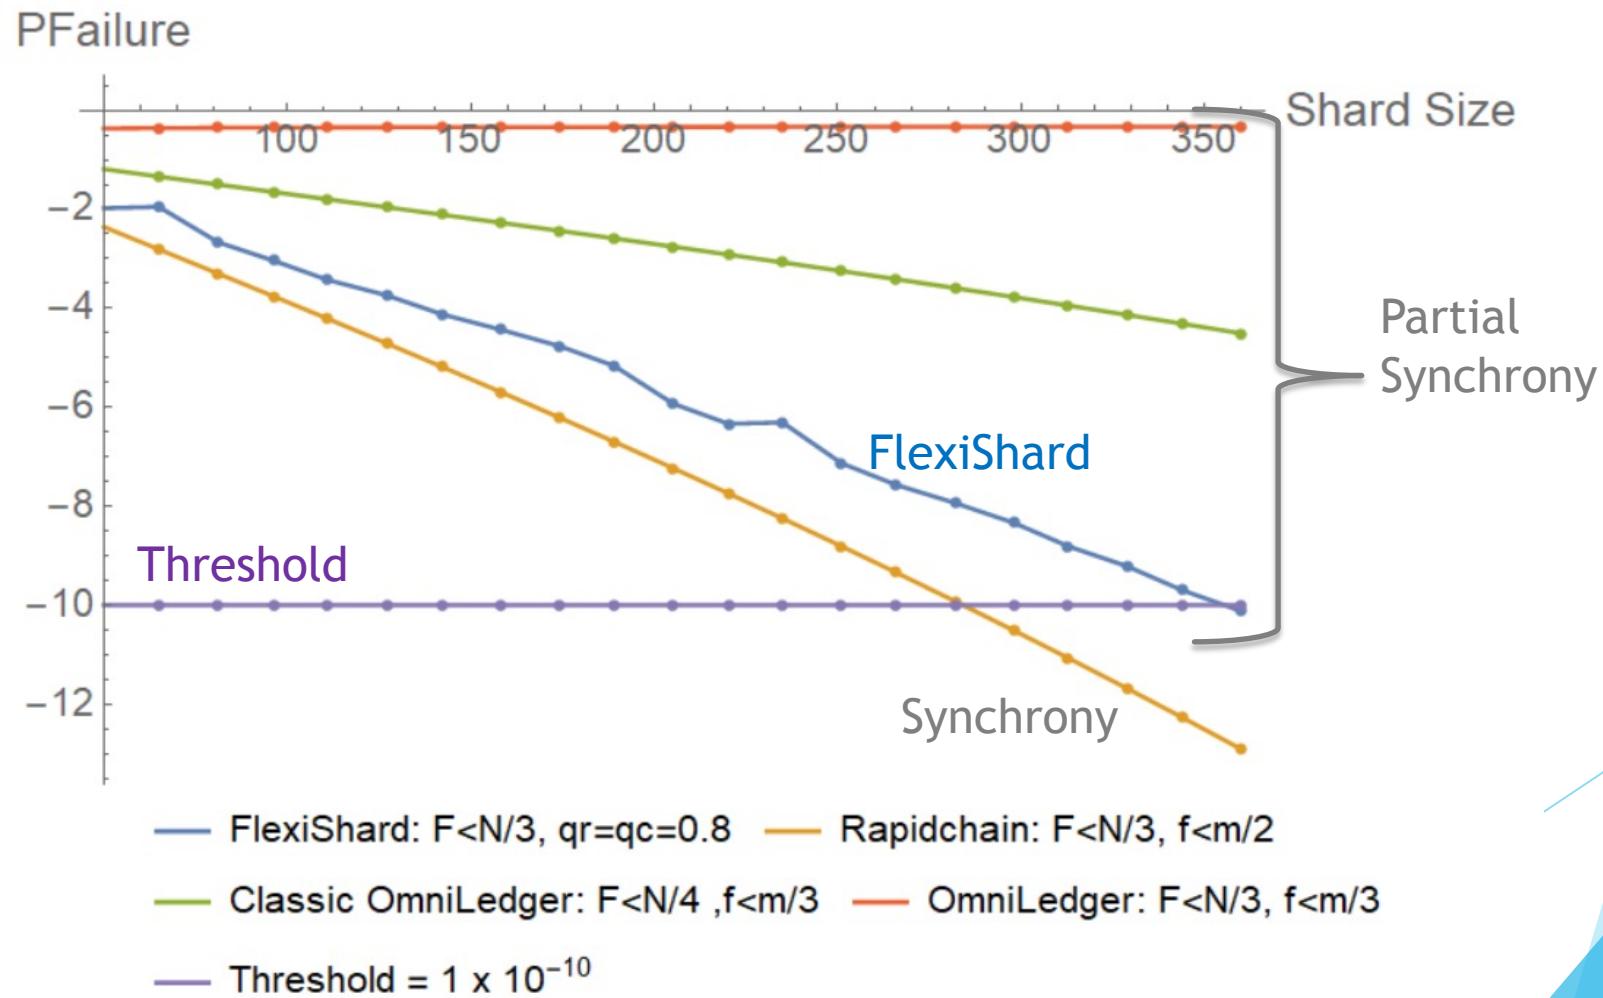

- ▶ $P_{FaultyFlexi} = 1 - P_{NonFaultyFlexi}$

FlexiShard's Schemes

- ▶ Many parameters can be varied
 - ▶ F , f , m , f_{abc} , f_{byz} , $byzProp$ or $byz:abc\ split$, qr , qc
 - ▶ Vary parameters to adapt to an ever-changing security environment
- ▶ Traditional Systems: F and f only, and rigid values
- ▶ Different ways to shard a system
- ▶ Schemes in the paper describe ways you can shard a system
- ▶ Examples
 - ▶ How to obtain good quorum sizes
 - ▶ How to obtain good shard sizes for fixed quorum sizes
 - ▶ How to obtain an OPTIMAL shard size under different environments

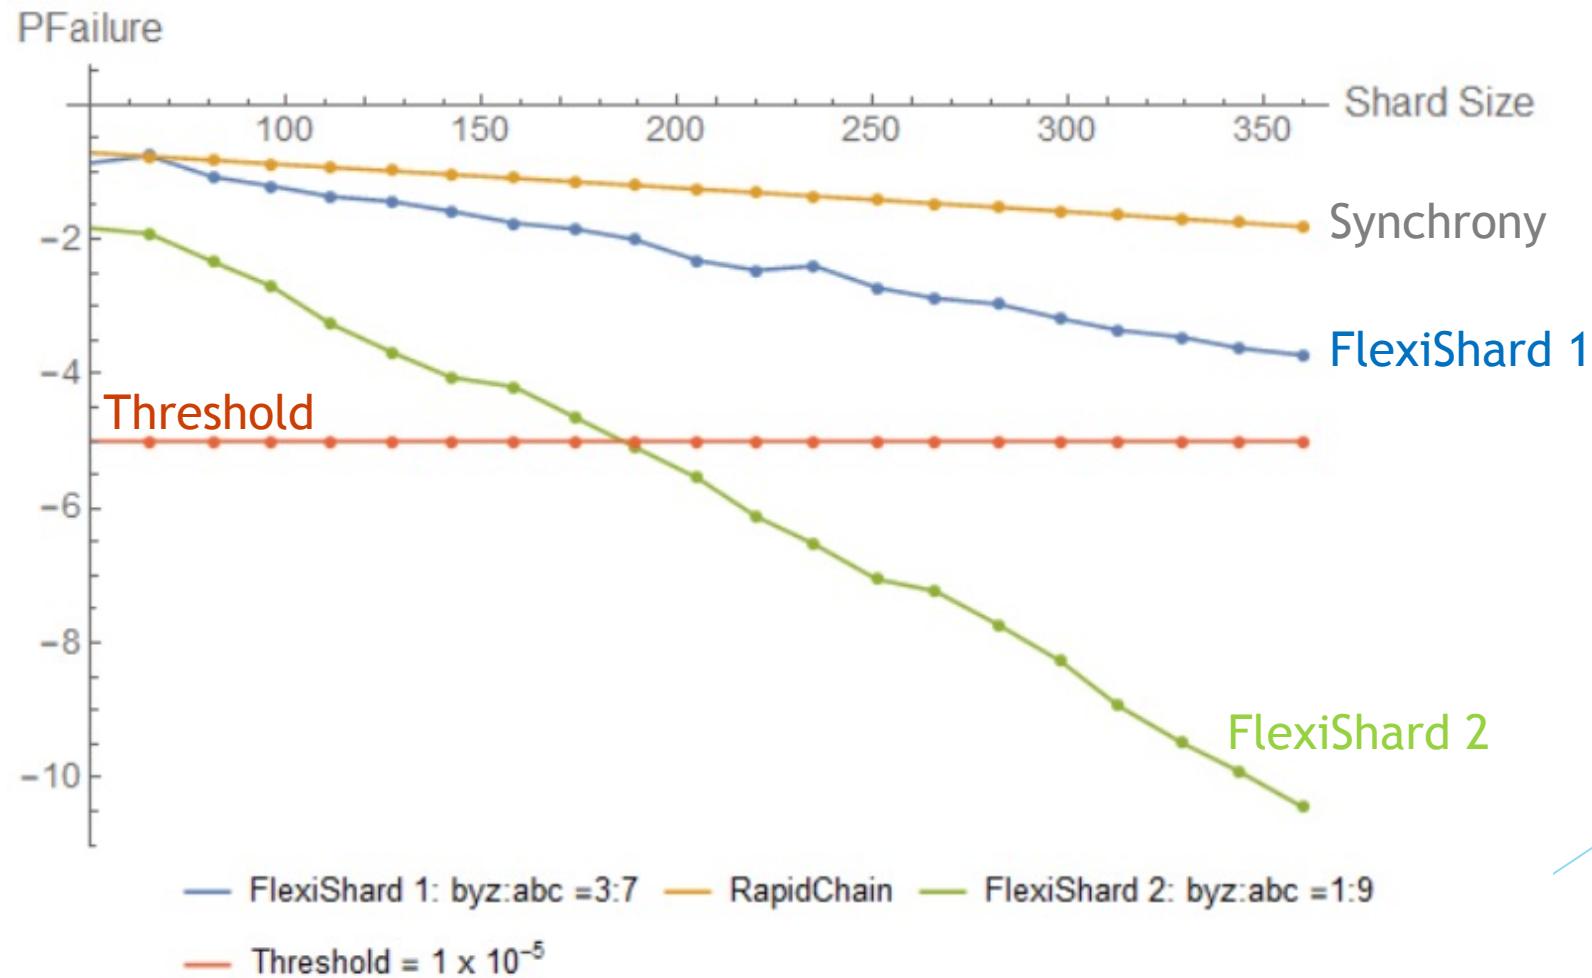

Results

Conventional bounds : $F < 0.33 N$

Results

Conventional bounds exceeded: $F < 0.45 N$

How is FlexiShard Useful?

Contemporary Sharding Systems

- ▶ Rigid parameters
- ▶ Difficult to adapt to a constantly-changing environment
- ▶ Synchrony
 - ▶ Intra-shard resiliency $< 1/2$
 - ▶ Total system resiliency $< 1/3$
 - ▶ Small shard
- ▶ Partial Synchrony
 - ▶ Intra-shard resiliency $< 1/3$
 - ▶ Total system resiliency $< 1/4$
 - ▶ Large shard size

FlexiShard

- ▶ Flexible parameters
- ▶ Can adapt accordingly & More Practical
- ▶ Intra-shard resiliency
 - ▶ Variable
 - ▶ Can exceed conventional bounds of $1/3$ or $1/2$
- ▶ Total system resiliency
 - ▶ Variable
 - ▶ Can exceed conventional bounds of $1/4$ or $1/3$
- ▶ Smaller shard size in Partial Synchrony
- ▶ Responsive
- ▶ Maximise performance potential
 - ▶ Small fault presence: extract more performance
 - ▶ Large fault presence: increase shard resiliency

Conclusion

- ▶ Hybrid Fault Model (More practical)
- ▶ Middle ground when total faults are within conventional bounds (1/3 or 1/4)
- ▶ Shards can also withstand more faults than conventional bounds in other cases

- ▶ Smaller shard sizes comparable to Synchrony; however in Partial Synchrony
- ▶ Responsive shards in Partial Synchrony (More Practical + Performance Gain)
- ▶ Middle ground between performance and security

THANK YOU

Appendix 1 - Components of a Sharding Blockchain

1. Node Selection (PoW, PoS)
2. Randomness generation (Secret Sharing, VFSS)
3. Node Assignment (Random Sampling + depends on consensus algorithm)
4. Intra-Shard Consensus (BFT - Sync or Partially Sync or Flexible)
5. Cross-shard Transaction Processing (Inter-Shard)
6. Shard Reconfiguration (Random, CuckooRule, Corruption Speed parameter)
7. Motivation Mechanism
